Results from post-task questionnaire

*Question 1: When you were playing the game with Hoki, how aware were you that she was playing the game at the same time in the other room?*

Participants gave a response on a scale from 1 (not at all) to 7 (completely). The mean response was 5.5 (median: 6; range 1-7).

*Question 2: Did the task feel different when you were playing against Hoki, compared with playing against the computer?*

15 participants (62.5%) responded no and 9 (37.5%) responded yes. If participants responded yes they were asked what the difference was. The 9 responses were as follows: 1) “When it was the computer I could feel that there was no other person”; 2) “The computer tends to surprise at the later half of the block. I felt refreshed when it changed from Computer to Hoki”; 3) “I was more conscious when playing with Hoki”; 4) “I felt more pressure playing with Hoki”; 5) “It was easier with the computer”; 6) “It felt more rewarding when playing with Hoki”; 7) “For the surprise trials I assume the computer was random, but I might guess when Hoki will do it”; 8) “Hoki produced more surprises”; 9) “I felt the difference between a person and a computer”.

*Question 3: Did you think differently or use different strategies when you were playing against Hoki versus playing against the computer?*

23 participants (96%) responded no and 1 (4%) responded yes (this participant said they tried harder to perform well in the human-partner condition).
Question 4: In actual fact, after you went into the scanner Hoki was no longer playing the game and you were actually playing against the computer the whole time. How surprised are you at this?

Participants gave a response on a scale from 1 (I knew this all along) to 7 (I had no idea). The mean rating was 5.9 (median: 6; range: 3-7).

Decoding intention-specific activity patterns

In the following set of analyses we searched for activity patterns that distinguished 1st-person versus 3rd-person intentions by training a classifier to distinguish 1st-person versus 3rd-person maps, where each map represented a subtraction between the two intention-states. For example, the 1st-person map for action-plans would represent a subtraction between 1st-person switch versus stay trials, while the 3rd-person map represented a subtraction between 3rd-person switch versus stay trials. Likewise, the 1st- and 3rd-person maps for goals represented subtractions between left versus right trials. These maps were generated separately for each scanning session, and we used the same procedure as the main decoding analyses to search for brain regions from which it was possible to decode 1st versus 3rd-person maps. We also used an equivalent procedure to decode 3rd-person intention maps generated from the human-partner versus computer-partner conditions.

*Table shows 3 local maxima more than 8.0 mm apart*

- Height threshold: $T = 3.48$, $p = 0.001$ (1.000)
- Extent threshold: $k = 42$ voxels, $p = 0.000$ (0.012)
- Expected voxels per cluster, $<k> = 2.351$
- Expected number of clusters, $<c> = 0.01$
- Degrees of freedom: $[1.0, 23.0]$
- FWHM: 9.1 9.0 9.0 mm mm mm; 3.0 3.0 3.0 (voxels)
- Volume: 2781 189 = 103007 voxels = 3454.1 resels
- Voxel size: 3.0 3.0 3.0 mm mm mm (resel = 27.53 voxels)
9. Human-partner versus computer-partner conditions for 3rd-person action-plans

*No significant clusters*

10. Human-partner versus computer-partner conditions for 3rd-person intentions (collapsing across goals and action-plans)

*No significant clusters*
